Langevin dynamic

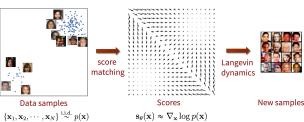

$$\mathbf{x}_{l+1} = \mathbf{x}_l + \frac{\eta}{2} \cdot \nabla_{\mathbf{x}_l} \log p(\mathbf{x}_l | \boldsymbol{\theta}) + \sqrt{\eta} \cdot \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim \mathcal{N}(0, \mathbf{I}).$$

Fisher divergence

$$D_{F}(\pi, p) = \frac{1}{2} \mathbb{E}_{\pi} \left\| \nabla_{\mathbf{x}} \log p(\mathbf{x}|\boldsymbol{\theta}) - \nabla_{\mathbf{x}} \log \pi(\mathbf{x}) \right\|_{2}^{2} \to \min_{\boldsymbol{\theta}}$$

Score function

Song Y. Generative Modeling by Estimating Gradients of the Data Distribution, blog post, 2021

Let perturb original data by normal noise $q(\mathbf{x}'|\mathbf{x},\sigma) = \mathcal{N}(\mathbf{x},\sigma^2\mathbf{I})$ $\pi(\mathbf{x}'|\sigma) = \int \pi(\mathbf{x})q(\mathbf{x}'|\mathbf{x},\sigma)d\mathbf{x}.$

Then the solution of

$$\frac{1}{2}\mathbb{E}_{\pi(\mathbf{x}'|\sigma)}\big\|\mathbf{s}_{\boldsymbol{\theta}}(\mathbf{x}',\sigma) - \nabla_{\mathbf{x}'}\log\pi(\mathbf{x}'|\sigma)\big\|_2^2 \to \min_{\boldsymbol{\theta}}$$

satisfies $\mathbf{s}_{\theta}(\mathbf{x}', \sigma) \approx \mathbf{s}_{\theta}(\mathbf{x}', 0) = \mathbf{s}_{\theta}(\mathbf{x}')$ if σ is small enough.

Theorem (denoising score matching)

$$\begin{split} & \mathbb{E}_{\pi(\mathbf{x}'|\sigma)} \big\| \mathbf{s}_{\boldsymbol{\theta}}(\mathbf{x}', \sigma) - \nabla_{\mathbf{x}'} \log \pi(\mathbf{x}'|\sigma) \big\|_{2}^{2} = \\ & = \mathbb{E}_{\pi(\mathbf{x})} \mathbb{E}_{q(\mathbf{x}'|\mathbf{x}, \sigma)} \big\| \mathbf{s}_{\boldsymbol{\theta}}(\mathbf{x}', \sigma) - \nabla_{\mathbf{x}'} \log q(\mathbf{x}'|\mathbf{x}, \sigma) \big\|_{2}^{2} + \text{const}(\boldsymbol{\theta}) \end{split}$$

Here $\nabla_{\mathbf{x}'} \log q(\mathbf{x}'|\mathbf{x},\sigma) = -\frac{\mathbf{x}'-\mathbf{x}}{\sigma^2}$.

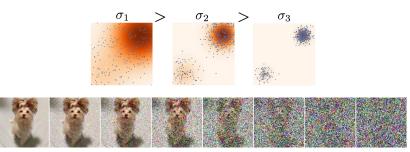

- ► The RHS does not need to compute $\nabla_{\mathbf{x}'} \log \pi(\mathbf{x}'|\sigma)$ and even more $\nabla_{\mathbf{x}'} \log \pi(\mathbf{x}')$.
- $ightharpoonup \mathbf{s}_{\theta}(\mathbf{x}', \sigma)$ tries to **denoise** a corrupted sample.
- ▶ Score function $\mathbf{s}_{\theta}(\mathbf{x}', \sigma)$ parametrized by σ .

Noise conditioned score network

- ▶ Define the sequence of noise levels: $\sigma_1 > \sigma_2 > \cdots > \sigma_T$.
- ▶ Train denoised score function $\mathbf{s}_{\theta}(\mathbf{x}', \sigma)$ for each noise level:

$$\sum_{t=1}^{T} \sigma_{t}^{2} \mathbb{E}_{\pi(\mathbf{x})} \mathbb{E}_{q(\mathbf{x}'|\mathbf{x},\sigma_{t})} \big\| \mathbf{s}_{\boldsymbol{\theta}}(\mathbf{x}',\sigma_{t}) - \nabla_{\mathbf{x}}' \log q(\mathbf{x}'|\mathbf{x},\sigma_{t}) \big\|_{2}^{2} \rightarrow \min_{\boldsymbol{\theta}}$$

▶ Sample from **annealed** Langevin dynamics (for t = 1, ..., T).

Song Y. et al. Generative Modeling by Estimating Gradients of the Data Distribution, 2019

NCSN training

- 1. Get the sample $\mathbf{x}_0 \sim \pi(\mathbf{x})$.
- 2. Sample noise level $t \sim U[1, T]$ and the noise $\epsilon \sim \mathcal{N}(0, I)$.
- 3. Get noisy image $\mathbf{x}' = \mathbf{x}_0 + \sigma_t \cdot \boldsymbol{\epsilon}$.
- 4. Compute loss $\mathcal{L} = \|\mathbf{s}_{\theta}(\mathbf{x}', \sigma_t) + \frac{\epsilon}{\sigma_t}\|^2$.

NCSN sampling (annealed Langevin dynamics)

- ► Sample $\mathbf{x}_0 \sim \mathcal{N}(0, \sigma_1 \mathbf{I}) \approx \pi(\mathbf{x}|\sigma_1)$.
- ► Apply *T* steps of Langevin dynamic

$$\mathbf{x}_l = \mathbf{x}_{l-1} + \frac{\eta_t}{2} \cdot \mathbf{s}_{\boldsymbol{\theta}}(\mathbf{x}_{l-1}, \sigma_t) + \sqrt{\eta_t} \cdot \boldsymbol{\epsilon}_l.$$

▶ Update $\mathbf{x}_0 := \mathbf{x}_L$ and choose the next σ_t .

Let
$$\mathbf{x}_0 = \mathbf{x} \sim \pi(\mathbf{x})$$
, $\beta_t \in (0,1)$. Define the Markov chain
$$\mathbf{x}_t = \sqrt{1-\beta_t} \cdot \mathbf{x}_{t-1} + \sqrt{\beta_t} \cdot \epsilon, \quad \text{where } \epsilon \sim \mathcal{N}(\mathbf{0},\mathbf{I});$$

$$q(\mathbf{x}_t|\mathbf{x}_{t-1}) = \mathcal{N}(\sqrt{1-\beta_t} \cdot \mathbf{x}_{t-1},\beta_t \cdot \mathbf{I}).$$

Statement 1

Let denote $\alpha_t = 1 - \beta_t$ and $\bar{\alpha}_t = \prod_{s=1}^t \alpha_s$. Then

$$q(\mathbf{x}_t|\mathbf{x}_0) = \mathcal{N}(\sqrt{\bar{lpha}_t}\cdot\mathbf{x}_0,(1-\bar{lpha}_t)\cdot\mathbf{I})$$

We are able to sample from any timestamp using only $x_0!$

$$\begin{split} \mathbf{x}_t &= \sqrt{\alpha_t} \cdot \mathbf{x}_{t-1} + \sqrt{1 - \alpha_t} \cdot \boldsymbol{\epsilon}_t = \\ &= \sqrt{\alpha_t} \big(\cdot \sqrt{\alpha_{t-1}} \mathbf{x}_{t-2} + \sqrt{1 - \alpha_{t-1}} \cdot \boldsymbol{\epsilon}_{t-1} \big) + \sqrt{1 - \alpha_t} \cdot \boldsymbol{\epsilon}_t = \\ &= \sqrt{\alpha_t} \alpha_{t-1} \cdot \mathbf{x}_{t-2} + \big(\sqrt{\alpha_t} \big(1 - \alpha_{t-1} \big) \cdot \boldsymbol{\epsilon}_{t-1} + \sqrt{1 - \alpha_t} \cdot \boldsymbol{\epsilon}_t \big) = \\ &= \sqrt{\alpha_t} \alpha_{t-1} \cdot \mathbf{x}_{t-2} + \sqrt{1 - \alpha_{t-1}} \alpha_t \cdot \boldsymbol{\epsilon}_t' = \\ &= \cdots = \sqrt{\bar{\alpha}_t} \cdot \mathbf{x}_0 + \sqrt{1 - \bar{\alpha}_t} \cdot \boldsymbol{\epsilon}, \quad \text{where } \boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \mathbf{I}). \end{split}$$

Forward gaussian diffusion process

$$q(\mathbf{x}_{t}|\mathbf{x}_{t-1}) = \mathcal{N}\left(\sqrt{1-\beta_{t}}\cdot\mathbf{x}_{t-1},\beta_{t}\cdot\mathbf{I}\right);$$

$$q(\mathbf{x}_{t}|\mathbf{x}_{0}) = \mathcal{N}\left(\sqrt{\bar{\alpha}_{t}}\cdot\mathbf{x}_{0},(1-\bar{\alpha}_{t})\cdot\mathbf{I}\right).$$

At each step we

- scale magnitude of the signal at rate $\sqrt{1-\beta_t}$;
- ▶ add noise with variance β_t .

Statement 2

Applying the Markov chain to samples from any $\pi(\mathbf{x})$ we will get $\mathbf{x}_{\infty} \sim p_{\infty}(\mathbf{x}) = \mathcal{N}(0, \mathbf{I})$. Here $p_{\infty}(\mathbf{x})$ is a **stationary** and **limiting** distribution:

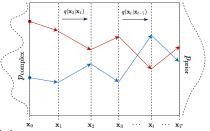

$$p_{\infty}(\mathbf{x}) = \int q(\mathbf{x}|\mathbf{x}')p_{\infty}(\mathbf{x}')d\mathbf{x}'.$$

$$p_{\infty}(\mathbf{x}) = \int q(\mathbf{x}_{\infty}|\mathbf{x}_0)\pi(\mathbf{x}_0)d\mathbf{x}_0 \approx \mathcal{N}(0,\mathbf{I})\int \pi(\mathbf{x}_0)d\mathbf{x}_0 = \mathcal{N}(0,\mathbf{I})$$

Forward gaussian diffusion process

Diffusion refers to the flow of particles from high-density regions towards low-density regions.

- 1. $x_0 = x \sim \pi(x)$;
- 2. $\mathbf{x}_t = \sqrt{1 \beta_t} \cdot \mathbf{x}_{t-1} + \sqrt{\beta_t} \cdot \epsilon$, where $\epsilon \sim \mathcal{N}(0, \mathbf{I})$, $t \ge 1$;
- 3. $\mathbf{x}_T \sim p_{\infty}(\mathbf{x}) = \mathcal{N}(0, \mathbf{I})$, where T >> 1.

If we are able to invert this process, we will get the way to sample $\mathbf{x} \sim \pi(\mathbf{x})$ using noise samples $p_{\infty}(\mathbf{x}) = \mathcal{N}(\mathbf{0}, \mathbf{I})$. Now our goal is to revert this process.

Summary

Gaussian diffusion process is a Markov chain that injects special form of Gaussian noise to the samples.

- Reverse process allows to sample from the real distribution $\pi(\mathbf{x})$ using samples from noise.
- Diffusion model is a VAE model which reverts gaussian diffusion process using variational inference.
- ► ELBO of DDPM could be represented as a sum of KL terms.
